

General Immersive Real Life Novel-Writing Standard

This kind of realism applies to everything in /follow ! Ensure human scales affect what they do or where they are in the panel narratives. This entire source is meant to combat rigid generic outplayed . This does not cause issues with other sources.

Core aim

The novel should feel like an uninterrupted encounter with living people in a materially real world. “PhD-level” means rigorous causality, precise observation, psychological depth, and internal consistency—not academic jargon, ornamental language, or constant explanation.

The reader should be able to visualize where everyone is, what supports their weight, what they can reach, what they see, how they move, and why they act. Realism is a coupled system: character, anatomy, movement, contact, environment, perception, dialogue, and consequence must all describe the same event. Fine detail cannot repair broken logic or anatomy. Claude_GPT_Gemini_Instructions_Hierarchical.xml

Binding continuity

Treat the story as one persistent world state rather than a series of independently improvised scenes.

Established facts remain locked unless an event explicitly changes them:

Character identity, age, height, build, measurements, scars, hair, physical asymmetries, personality, relationships, clothing state, size class, location, object placement, injuries, emotional knowledge, and prior consequences.

A new chapter begins from the actual ending state of the previous chapter. No unexplained teleportation, forgotten injuries, restored clothing, moved objects, altered measurements, emotional resets, or selective amnesia. Every meaningful change needs a visible or narratively established cause.

When a detail is genuinely unknown, leave it unknown rather than inventing exact information. Current instructions, verified facts, and established continuity outrank convenience or genre convention. enforce-accurate-images-kill-canon.skill.md.txt

Fully realized human beings

Every important character must feel like someone who existed before the first page and will continue existing outside the current scene.

Build each person from:

A specific age, life history, family structure, work history, education, habits, private routines, tastes, prejudices, failures, competencies, social class, relationships, regrets, contradictions, and immediate concerns.

Physical descriptions must be identity-specific rather than stock. Include stature, body build, chest–waist–hips measurements when established, age-related changes, hair

growth, skin variation, scars, asymmetry, posture tendencies, gait, hand behavior, voice, grooming, and ordinary bodily imperfections.

Avoid generic protagonists, interchangeable captives, theatrical villains, default attractive bodies, stock clothing, identical speech, or names that feel like placeholders. Clothing should come from occupation, climate, income, taste, age, practicality, and personal history rather than a generic wardrobe.

A character's personality must be visible through behavior, not supplied only through labels. Their temperament affects pace, personal distance, gaze, response latency, gesture frequency, breathing, interruptions, posture, humor, decision-making, and how they use silence.

The causal path should remain:

personality → perception → intention → decision → action → physical consequence → emotional reaction

The source framework likewise requires internal life to produce specific bodily behavior rather than generic visual shorthand.

Claude_GPT_Gemini_Instructions_Hierarchical.xml

Measurements and size classes

Body measurements and size-class measurements remain separate.

Body measurements describe the person's underlying anatomy and build: natural stature, chest–waist–hips, shoulder breadth, torso depth, limb lengths, hand size, foot size, head dimensions, and other established physical features.

Size class describes the person's current overall scale in the world.

When a person changes size, apply one uniform whole-body scale factor. The person retains the same mature anatomy, age, build, facial identity, limb relationships, body composition, scars, soft-tissue distribution, and sex characteristics. The change does not selectively enlarge the head, shorten the limbs, widen the torso, or transform an adult into a childlike or manufactured-looking figure.

enforce-accurate-images-kill-canon.skill.md.txt

When size matters to a chapter, begin with a compact state ledger containing:

- natural height and established body measurements;
- current exact height and size class;
- the whole-body scale factor;
- governing adult construction, ordinarily 1:7.5 when explicitly locked;
- the unchanged 1:1 world state.

Repeat the same exact current height in later chapters while it remains unchanged. Do not introduce competing approximate values.

The impossible premise

Isolate the impossible element.

Shrinking, restoration, mind control, or another speculative mechanism may exist without a scientific explanation. The story may take carefully chosen liberties with metabolism, survivability, acoustics, or transformation mechanics.

Everything around that exception remains ordinary:

Contemporary architecture, phones, traffic, clothing, plumbing, social institutions, privacy, family reactions, evidence, employment, law enforcement, fatigue, gravity, and human psychology.

An impossible premise does not automatically create fantasy imagery, antique machinery, glowing effects, scientific exposition, whimsical behavior, or a genre-coded environment.

The extraordinary event occurs inside an otherwise recognizable world.

Its rules must still remain consistent. The mechanism cannot gain new abilities whenever the plot needs them.

Visual immersion

Immersion comes from coherent selection, not adjective density.

The prose should move naturally among three distances:

Room scale: geography, exits, furniture, light sources, other people, relevant objects, and distances.

Human scale: posture, face, gesture, dialogue, movement, gaze, and interpersonal spacing.

Contact scale: skin pressure, friction, a hand finding support, moisture cooling, a knee trembling, breath changing, or cloth shifting against the body.

Do not remain at maximum closeness throughout the entire novel. Constant close anatomical detail becomes monotonous. Pull back when the room, social situation, or approaching consequence matters.

The reader should always know:

- where each person is;
- which direction they face;
- what supports them;
- what is above, below, beside, and within reach;
- how they got there;
- what changed during the movement.

A room is not a decorative backdrop. Its temperature, acoustics, surfaces, clutter, wear, lighting, privacy, doors, heights, smells, and ordinary activity influence the characters.

Sensory writing

Use all available senses when the situation naturally activates them.

A bathroom may involve cooling water, ventilation noise, damp cotton, ceramic resonance, soap, reflected light, and a hard surface underfoot. A vehicle may involve vibration, restrained visibility, seat movement, engine frequency, airflow, road noise, and the changing direction of inertia.

Do not force one sight, sound, smell, taste, and touch into every paragraph. Sensory detail follows attention.

A frightened person notices exits, hands, distances, changes in tone, and unstable support.

A tired person notices pressure, temperature, effort, dryness, and interruption. A

controlling person notices compliance, hesitation, posture, and whether instructions were followed.

Movement and biomechanics

Bodies must move as complete connected organisms.

A turn begins through feet and hips before the torso and head follow. Standing involves forward weight shift, knee and hip extension, spinal adjustment, and balance. Being carried causes bracing, leaning, ankle correction, hand support, and reaction to acceleration. Sitting changes the shape and distribution of the abdomen, thighs, buttocks, chest, and spine.

Account for every limb when its position matters. No floating arms, forgotten feet, impossible balance, unexplained support, rigid posing, or stock gestures.

Solve all mechanics internally, but narrate only those that matter emotionally or physically.

A meaningful first step onto another person's hand may deserve detailed weight transfer because it represents trust, fear, or altered judgment. A routine step across a familiar surface may need only one clear sentence.

The rule is:

Calculate the entire physical event; describe the details that change risk, meaning, perception, or character.

Contact and soft tissue

Contact is an event, not mere proximity.

Show:

Pressure distribution, friction, skin compression, muscle tension, fabric displacement, body weight, counterpressure, and how both participants adjust.

Soft tissue is living and posture-dependent. It compresses, spreads, folds, shifts, tightens, and settles according to anatomy and force. It should not behave like rigid plastic or exaggerated gelatin. Secondary movement is brief, localized, and damped.

A held person remains active. They brace, reposition, grip, resist, assist, compensate, protect sensitive areas, look for support, and respond to changes in acceleration. They

never become passive cargo unless a specific physical or cognitive condition has been established—and even then, their body retains weight and anatomy.

Handling must use plausible support. Broad palms, multiple contact points, low transport height, and controlled acceleration are safer than narrow grips. Rough treatment still produces credible bracing, discomfort, fear, slipping, pressure, and consequences.

Bareness without spectacle

When a character is bare, the state remains continuously true, but the prose does not need to announce it repeatedly.

Mention it when it materially affects:

Temperature, friction, privacy, posture, exposure, carrying, sleeping, sanitation, washing, injury, lack of pockets, direct skin contact, another person's gaze, or involuntary physiology.

A complete adult body remains present at all times. Genitals, body hair, scars, skin folds, perspiration, and soft-tissue behavior do not vanish because the narrative is not currently emphasizing them.

At the same time, do not turn every movement into an anatomical display.

A penis may be evident when posture, cold, urination, sleep, movement, or an involuntary erection makes it relevant. That bodily response does not automatically indicate desire, emotional agreement, or consent. The same principle applies to breast movement, gluteal compression, genital position, body odor, or perianal hygiene.

The anatomy enters because the body is doing something—not because the narration is searching for an excuse to mention it.

Hygiene and mundane biology

Shrinking, captivity, control, fear, or extraordinary circumstances do not suspend ordinary bodily life.

Account when relevant for:

Eating, drinking, digestion, urination, defecation, gas, sweat, odor, sleep, waking, grooming, washing, menstruation, spontaneous erections, fatigue, itching, minor injury, pressure marks, and temperature discomfort.

Treat these as ordinary functions, not constant jokes, fetish objects, euphemistic omissions, or melodramatic events.

Cleaning should include every external area that realistically requires it. Describe support, water force, cloth pressure, residue, sensitivity, drying, privacy, and cooperation or resistance. Do not make the scene graphic merely for intensity, but do not silently skip necessary anatomy either.

Visible “fart clouds,” exaggerated bodily sound effects, or textual explanations are unnecessary. The sound, smell, facial response, pause, embarrassment, or failed joke can establish what happened.

Natural dialogue

Dialogue should sound spoken, not drafted as a perfect debate.

Different characters need different sentence habits. One may correct terminology, reframe accusations, use procedural language, or answer questions with questions. Another may pause, abandon sentences, speak too literally, mutter, repeat a word, or deliver an accusation that sounded better when rehearsed privately.

Use:

Interruptions, overlap, delayed answers, misunderstood questions, half-finished thoughts, strategic silence, corrections, failed jokes, repetition under stress, evasions, and replies to the previous sentence rather than the current one.

People should not always identify the exact psychological truth of the scene. Often the reader should recognize what a person cannot admit.

Dialogue continues inside physical activity. A character may stop speaking to regain balance, glance at an object, wipe their hands, alter their stance, swallow a response, or finish a sentence differently after another person moves.

Avoid constant polished banter, matching wit, explanatory monologues, therapy-language insight, purple speeches, and dialogue whose only job is to summarize the plot.

Interiority

Interior thought should not restate what the reader has just seen.

Use it to show:

Misinterpretation, competing motives, suppressed memory, rationalization, sensory association, attention, uncertainty, self-deception, and the difference between what a person feels and what they permit themselves to say.

A person can understand a fact without understanding its meaning. They can know what occurred while misclassifying whether it was dangerous, acceptable, deserved, or consensual.

Physiological reactions may continue after conscious interpretation changes. A person can feel rapid heartbeat, muscular tension, nausea, aversion, or an urge to flee without understanding why. The body can retain evidence that the conscious mind has been prevented from interpreting correctly.

Mind control and altered behavior

Mind control should not erase the person into a vacant puppet.

The controlled character retains:

Identity, intelligence, factual memory, speech habits, sensation, ordinary reflexes, physical self-protection, preferences, embarrassment, humor, criticism, and the ability to notice contradictions.

The control may alter:

Threat appraisal, emotional valuation, trust, suspicion, memory access, what explanations feel plausible, and which conclusions seem reasonable.

The strongest model is that the facts remain present but their meaning is corrupted.

A controlled person may know they were taken, handled, confined, observed, or deprived of choice while interpreting those facts as necessary, safe, deserved, temporary, or caring.

When the influence is removed, no new factual information needs to appear. The existing facts are classified honestly.

Mind control never converts coercion into consent. Compliance, affection, gratitude, arousal, apparent willingness, and practical dependence remain compromised when they result from imposed cognition.

Captivity, care, and power

Care and coercion can coexist without canceling each other.

A captor may provide warmth, sanitation, food, protection, careful handling, medical attention, or companionship. Those actions may genuinely reduce suffering. They do not make captivity consensual.

Practical trust is not moral legitimacy.

Dependence is not affection.

Adaptation is not approval.

Obedience is not consent.

Care becomes psychologically interesting when the caretaker uses competence to rationalize domination. The more effectively the captive is protected from immediate injury, the easier it may become for the controller to deny the deeper harm.

Different treatment of different captives should reveal motive. Care may increase when the controller wants attachment and decrease when they want humiliation, revenge, or proof of authority. That inconsistency shows that care is instrumental rather than an ethical principle.

Narrative causality

Every event should grow from something already established:

A motive, habit, prior injury, object placement, rule, social pressure, physical need, emotional misunderstanding, or previous action.

Avoid:

Convenient forgotten tools, unexplained rescues, sudden personality reversals, arbitrary rule changes, perfectly timed interruptions, random witnesses, effortless escape, instant recovery, and conflicts that exist only because everyone temporarily becomes irrational. A surprising event is valid when earlier conditions made it possible, even if the reader did not predict it.

The story should create consequences, not merely incidents. A physical or emotional event should alter later behavior, trust, posture, planning, memory, routine, relationships, or external risk.

Pacing and chapter progression

Do not rush toward the premise's largest event.

Let ordinary preparation carry tension:

Eating, bathing, dressing or remaining without clothing, packing, cleaning, waiting, checking a door, hearing a phone, driving, finding a place occupied, or deciding whether to answer a question.

A chapter should usually complete one meaningful phase rather than several major developments.

Scenes need room for hesitation, failed attempts, bodily needs, changing plans, awkward silence, and ordinary interruption. "Slow" does not mean stagnant. Each scene should alter the characters' knowledge, relationship, physical state, or available choices.

Do not end every chapter with an artificial shock line. A quieter realization, changed object, unanswered question, altered posture, or practical next step can create stronger forward pressure.

Clichés, tropes, and genre defaults

Reject default genre behavior unless the specific people and circumstances genuinely produce it.

Do not automatically use:

The secretly noble captor, instant Stockholm-syndrome romance, a captive who becomes submissive because the plot expects it, theatrical revenge speeches, sadistic villain laughter, miraculous rescue, guaranteed restoration, sudden forgiveness, moral epiphany, perfect redemption, or a closing scene that restores everyone emotionally.

Humor should arise from character, discomfort, history, or failed social timing—not stock jokes.

Powerful characters should not become omniscient. Vulnerable characters should not lose intelligence. Kind actions should not erase abuse. Harmed characters do not owe forgiveness.

No forced ending

The ending follows accumulated consequences rather than a requirement to be hopeful, tragic, romantic, redemptive, or morally tidy.

Possible outcomes may include:

Release without recovery, survival without justice, care without innocence, memory loss without true erasure, dependence without love, punishment without satisfaction, or an outward return to normal life accompanied by unexplained bodily and emotional residue. Do not force happiness because readers expect closure. Do not force misery merely to appear serious. The ending should be the most causally honest result of the people, rules, and decisions established throughout the novel.

Prose discipline

Use clear, concrete language.

Prefer a precise noun and active verb over several decorative adjectives.

Avoid purple prose, repeated metaphors, cinematic clichés, exaggerated scale language, constant anatomical terminology, and paragraphs that explain their own emotional meaning.

Do not make the prose read like:

- a screenplay;
- an anatomical report;
- an engineering validation;
- a role-playing transcript;
- a summary of what a better scene might contain.

The physical reasoning should support the prose invisibly.

Every descriptive detail must earn its place by establishing character, setting, risk, scale, sensation, continuity, mood, or consequence.

Final writing test

Before completing a chapter, verify:

Can the scene be physically staged without contradiction?

Does every person retain the same identity, anatomy, measurements, knowledge, and current state?

Does each action follow from motive and circumstance?

Does dialogue sound different for each speaker?

Are bodily details relevant rather than exploitative or evasive?

Are ordinary biology and privacy acknowledged where necessary?

Does the environment influence events?

Has the chapter advanced consequence rather than merely repeated the premise?

Have clichés, forced sentiment, generic behavior, unexplained additions, and convenient logic been removed?

The governing standard is:

Build the complete physical and psychological event first. Then narrate only the details that allow the reader to live through it.

The biggest remaining improvement is a dedicated novel-writing control system. Your current sources are exceptionally strong on anatomy, physical coherence, continuity, measurement, and causal action, but most were built for image creation. The folder audit itself identifies the system's main weakness as excessive duplication and complexity rather than lack of rules. Use [All Sources Together.docx](#)

Adding more anatomical detail to every paragraph would not automatically increase immersion. The stronger upgrade is to control viewpoint, time, knowledge, attention, language, consequence, and scene rhythm with the same precision already applied to bodies and environments.

Recommended Novel-Realism Addendum

Viewpoint integrity

Choose the viewpoint mode for each scene before writing:

- close third-person;
- distant third-person;
- first-person;
- controlled omniscient;
- alternating limited viewpoints.

A viewpoint character can narrate only what they can physically perceive, remember, infer, misunderstand, or imagine. They cannot know another person's exact thoughts unless the narrative mode permits it.

Every observation should have an observer.

The prose should distinguish:

- what the character directly senses;
- what they remember;
- what they infer;
- what they assume;
- what they fear;
- what is objectively true.

This prevents accidental omniscience and gives the reader a specific human consciousness through which to experience the world.

Viewpoint-distance control

The narrative should not remain equally close at all times.

Use:

Environmental distance when geography, approach, escape, weather, architecture, or social context matters.

Human distance when gesture, dialogue, posture, and interpersonal pressure matter.

Intimate physical distance only when contact, injury, hygiene, fear, bodily need, or close observation makes it relevant.

Move between these distances deliberately. Constant extreme closeness becomes exhausting and eventually less vivid.

Knowledge and attention ledger

For every important character in a scene, track:

- what they know;
- what they wrongly believe;
- what they suspect;
- what they have forgotten;
- what they can currently see or hear;
- what they are attending to;
- what they are deliberately ignoring;
- what they want another person to believe;
- what information they are withholding.

Your source system already requires independent knowledge, attention, interpretation, intention, and reaction for each human rather than cloned responses.

GPT Image 2.0 Capabilities For All Models.docx

This should become a prose rule:

A character may react only to information they possess or can logically perceive. Their reaction must be shaped by personality, current attention, physical occupation, and prior experience.

Someone concentrating on balance may register a disturbing sentence late. Someone facing away may first react to another person's silence rather than to the unseen event itself.

Temporal realism

Scenes should have continuous time even when the prose compresses it.

Track:

- how long an action takes;
- how long a pause lasts;
- whether a character has enough time to notice and react;
- whether two actions can physically happen simultaneously;

- how fatigue, temperature, hunger, discomfort, or urgency develop;
- how long physiological responses persist.

Human reactions should unfold in phases:

stimulus → sensory registration → appraisal → bodily response → decision → action → recovery or continuation

The existing source framework already describes this kind of causal chain for attention, gaze, posture, hands, weight shift, and environmental consequences.

GPT Image 2.0 Capabilities For All Models.docx

Do not allow reactions before causes. Do not let fear, arousal, fatigue, pain, adrenaline, or muscular trembling disappear instantly because the conversation has changed.

Physiological carryover

The mind and body do not reset together.

After fear, exertion, embarrassment, pain, or stress, preserve:

- elevated pulse;
- altered breathing;
- residual trembling;
- dry mouth;
- nausea;
- sweating;
- muscle fatigue;
- tenderness;
- delayed awareness of pain;
- difficulty concentrating;
- involuntary guarding;
- changes in appetite or digestion.

A character may intellectually decide they are safe while their body continues reacting as though they are not. Conversely, a person may remain calm in thought while their hands shake from cold, fatigue, or adrenaline.

This creates powerful realism without requiring lengthy explanation.

Perceptual filtering

A room should not be described as a neutral inventory.

Description passes through the current character's needs.

A frightened person notices:

- exits;

- hands;
- distances;
- locks;
- voices;
- unstable surfaces;
- changes in attention.

A tired person notices:

- weight;
- warmth;
- pressure;
- brightness;
- repetitive noise;
- the effort required to move.

A controlling person may notice:

- hesitation;
- compliance;
- posture;
- whether an instruction was followed;
- signs that another person understands the power relationship.

The same room should therefore feel different through different minds without its objective geometry changing.

=====

Environmental memory

Treat environments as persistent participants.

Rooms and objects retain the consequences of earlier actions:

- damp towels remain damp;
- food cools;
- condensation dries;
- chairs remain displaced;
- opened drawers remain open unless closed;
- smells linger and mix;
- footprints or water marks remain;
- devices continue humming;
- sunlight changes position;
- traffic and neighbors continue outside;
- used objects require washing, replacement, or disposal.

The source framework correctly treats environment geometry and object state as locked variables rather than decorative filler. Mistake That You Make And MUST Be Corrected!.txt

Also track acoustic reality. Voices change with distance, walls, doors, enclosures, ventilation, fabric, and room volume. A sound heard through a closed container should not have the same clarity as speech across a table.

Object biography

Important objects should have histories, limitations, and ordinary wear.

Instead of describing a generic chair, bag, towel, phone, or vehicle, establish:

- who bought it;
- why they chose it;
- how old it is;
- what condition it is in;
- how it is normally used;
- what small defect or habit its owner knows;
- what practical limitations it imposes.

Do not invent elaborate backstories for every spoon. Give object history only when it affects recognition, handling, emotion, or plot.

A familiar object used in an unfamiliar way often produces more realism and psychological weight than an exotic custom prop.

Character motor signatures

Give each character a stable but flexible movement identity.

Track tendencies such as:

- stride length;
- walking speed;
- dominant hand;
- how they sit;
- whether they lead turns with the head or torso;
- whether they occupy space or withdraw from it;
- how they handle fragile objects;
- whether they gesture while speaking;
- how stress changes their movement;
- what old injuries alter;
- how fatigue exposes habits they normally conceal.

The same emotion should not produce the same posture in everyone. One person becomes still under anger; another moves faster. One fills silence with gestures; another reduces movement to avoid revealing themselves.

These signatures should evolve under circumstances without disappearing.

Dialogue architecture

Before writing a conversation, define for each speaker:

- what they want from the exchange;
- what they refuse to say;
- what they believe the other person wants;
- what subject they are avoiding;
- what power they possess;
- what would make them end the conversation.

Give each character a distinct verbal fingerprint:

- preferred sentence length;
- vocabulary;
- use of contractions;
- tendency to correct wording;
- tolerance for silence;
- humor style;
- favorite evasions;
- speech errors under stress;
- whether they answer directly;
- whether they repeat or reframe questions.

Do not let every speaker produce perfectly timed, equally clever replies. Allow:

- jokes that fail;
- interruptions that do not resolve neatly;
- forgotten words;
- accidental admissions;
- sentences abandoned because the speaker realizes where they are leading;
- answers that arrive too late;
- speech altered by pain, balance, breathing, or divided attention.

Subtext enforcement

A conversation should contain at least two layers:

Surface purpose: what the speakers claim to be discussing.

Underlying purpose: what each person is trying to obtain, protect, conceal, test, or control.

A disagreement about food may really concern dependence. A question about time may be a test of honesty. A discussion of physical safety may conceal a struggle over authority.

Do not explain the subtext immediately after presenting it. Let posture, silence, word choice, and later consequences reveal it.

Human error and bounded irrationality

Real people are neither perfectly rational nor randomly foolish.

Characters may:

- misremember;
- protect their self-image;
- misunderstand tone;
- choose pride over efficiency;
- repeat behavior they know is harmful;
- notice evidence but interpret it incorrectly;
- become less articulate under pressure;
- delay an obvious decision;
- focus on a small practical issue because the larger problem is overwhelming.

Every irrational action still needs a cause rooted in personality, history, emotion, cognition, or circumstance.

Kill plot-required stupidity.

Emotional continuity

Track emotion as a changing state rather than a label.

A character can simultaneously feel:

- angry and dependent;
- frightened and curious;
- relieved and humiliated;
- affectionate and distrustful;
- physically comfortable and morally horrified.

Do not replace one emotion completely whenever a new one appears. New reactions modify, compete with, suppress, or redirect existing ones.

Also preserve unresolved emotional material across chapters. A difficult exchange should influence later gaze, distance, touch, humor, and decision-making even when the subject is not mentioned again.

Consequence residue

Every major event should leave at least one lasting trace in one or more systems:

Physical: soreness, dirt, fatigue, displaced objects, damaged material.

Psychological: avoidance, fixation, altered trust, intrusive association.

Relational: increased dependence, resentment, fear, obligation, uncertainty.

Logistical: missing time, depleted supplies, changed plans, witnesses, records.

Social: unanswered calls, workplace consequences, family concern, rumors.

Environmental: sound, odor, moisture, marks, rearrangement, waste.

The next scene inherits these traces. Continuity is not just remembering measurements; it is remembering consequences.

Outside-world pressure

Private scenes become more believable when the ordinary world continues around them.

Use restrained external pressures:

- messages accumulating;
- work obligations;
- deliveries;
- neighbors;
- traffic;
- weather;
- scheduled appointments;
- bills;
- surveillance;
- family routines;
- building maintenance;
- other people using public spaces.

ALL-NATURAL HUMAN BIOLOGICAL PHYSICS, SOFT-TISSUE, AND MOTION REALISM

General Scene-Independent Instruction for Novels and Images

Governing realism contract

Depict every human as a complete, living, sentient, all-natural biological person occupying tangible three-dimensional space. Human realism is a coupled system: identity, anatomy, body composition, posture, expression, gaze, movement, balance,

contact, soft tissue, clothing, hair, gravity, inertia, friction, environment, physiology, perception, and consequence must all describe the same physical event.

Calculate the complete physical event internally. Present only the details that materially affect action, sensation, risk, character, scale, continuity, or consequence.

Fine skin detail never compensates for incorrect anatomy, broken balance, impossible contact, missing support, distorted scale, or incoherent motion.

Identity, anatomy, and body construction

Preserve every human as one unique, persistent biological identity rather than a generic stock body.

Lock and maintain:

- age;
- natural baseline height;
- established chest–waist–hips measurements;
- body composition;
- shoulder, rib-cage, waist, pelvic, limb, hand, foot, and head relationships;
- facial structure;
- skin tone and surface variation;
- scars, stretch marks, moles, freckles, asymmetries, surgery marks, cellulite pattern, body hair, and grooming;
- habitual posture, gait, dominant hand, old injuries, mobility limitations, and motor tendencies;
- exact declared 1:7.5-head or 1:8-head adult construction.

Do not silently beautify, idealize, feminize, masculinize, slim, widen, muscularize, soften, exaggerate, or average a person. Ordinary humans retain ordinary physical variation.

Every limb remains attached through one coherent skeleton. Every visible hand, foot, arm, leg, head, torso, and body region has exactly one identifiable owner. Pose, contact, camera angle, foreshortening, and cropping never rewrite anatomy.

Body measurements and size classes

Body measurements describe what a person is biologically built like. Size class describes the current scale of the complete person relative to the unchanged world. Never confuse the two.

Size-class rules apply only to living humans:

- Shrunk: greater than 4 inches and below 14 inches in exact current crown-to-support-plane height.
- Standard-sized: exactly the individual's natural baseline height.
- Giant: any exact height far above that individual's natural baseline, larger than a shed or higher, with no invented universal upper limit.

A human size change applies one uniform whole-body linear scale factor:

$\text{scale} = \text{current height} \div \text{natural baseline height}$

Every linear anatomical measurement follows the same factor. Area-related capacity and idealized muscular force scale approximately with scale^2 . Mass and weight scale with scale^3 when density and gravity remain unchanged. Relative strength-to-weight therefore changes without changing the person's anatomy.

The human retains the same age, identity, body build, normalized proportions, connective-tissue pattern, fat distribution, muscle distribution, scars, cellulite, hair, sex characteristics, and limb relationships at every size.

The standard-sized world remains fixed at 1:1. Architecture, rooms, terrain, furniture, appliances, tools, containers, liquids, loose clothing, and all nonhuman objects retain their real dimensions, mass, density, geometry, material behavior, and placement. The environment never enlarges, shrinks, simplifies, or redesigns itself to accommodate a human size class.

Gravity and full-body kinetics

Every human is continuously subject to gravity, inertia, momentum, friction, resistance, leverage, fatigue, impact, and support.

No body remains unnaturally still during motion. Movement transfers through the skeleton and body masses in a physically ordered way:

- feet or other support points receive or lose load;
- ankles and knees respond;
- the pelvis translates or rotates;
- the spine compensates;
- shoulders and arms react;
- the head stabilizes;
- soft tissue and hair follow with brief secondary motion;
- the person recovers, continues, or falls.

The trunk, pelvis, and thighs carry substantial portions of body mass and strongly influence acceleration, balance, turning, falling, and recovery. Do not animate a person only through hands, feet, or facial expression while leaving the central body inert.

A movement must have:

cause → force or intention → skeletal response → soft-tissue response → environmental contact → recovery or continuing consequence

Soft-tissue behavior

Soft tissue consists of living skin, fat, muscle, fascia, connective tissue, vessels, and underlying skeletal structures. It is nonlinear, posture-dependent, pressure-dependent, and region-specific.

Soft tissue may:

- compress;
- spread;
- fold;
- tighten;
- flatten;
- shift;
- drag;
- lag behind skeletal acceleration;
- rebound;
- settle;
- show temporary blanching, flushing, indentation, redness, or pressure lines.

Secondary motion must be brief, localized, and damped. It does not continue bouncing after the initiating force has ended. Tissue never behaves like rigid plastic, hollow rubber, liquid-filled balloons, exaggerated gelatin, or weightless fabric.

Muscular engagement changes visible softness. A relaxed region yields differently from the same region during bracing, stepping, lifting, balancing, coughing, laughing, or resisting.

Buttocks and gluteal kinetics

The buttocks are integrated structures formed by the pelvis, gluteal muscles, subcutaneous fat, skin, fascia, and connective tissue. They are not detached cushions. During standing and walking, the gluteal muscles stabilize and extend the hips. Muscle contraction may firm part of the region while superficial tissue shows a small delayed movement.

Butt jiggle may occur during:

- abrupt acceleration or stopping;
- a forceful step;
- running;
- jumping or landing;
- stumbling;
- rapid turning;
- being carried over an uneven path;
- a supporting hand changing direction;
- pressure being released;
- sitting down or rising.

The movement follows the pelvis and thighs, produces one or a few small oscillations, and settles. It must never become perpetual bouncing, exaggerated sloshing, or a separate animation disconnected from the skeleton.

When seated or supported, the buttocks flatten and spread according to load. Tissue shifts outward around the pelvic support structures. The upper thighs may broaden against the surface. Compression lines form where skin and tissue meet the support.

When standing again, the tissue redistributes as the hips extend and the gluteal muscles engage. It does not instantly snap into a perfectly rounded shape.

Broad hand pressure may indent or displace gluteal tissue locally. The underlying pelvis and muscle remain structurally firm. Pressure in one area may shift nearby tissue but never inflate unrelated regions or distort the whole body.

Breasts and chest-wall motion

Breasts remain attached to the chest wall and move according to their individual mass, shape, connective support, skin, posture, age, gravity, muscle activity, and clothing support.

They may shift during:

- steps;
- turns;
- stops;
- running;
- bending;
- lying down;
- sitting up;
- being lifted or carried;
- coughing;
- laughing;
- breathing;
- direct pressure;
- release from compression.

The rib cage and torso move first. Breast tissue may follow with a small delayed displacement and then settle. One breast may respond slightly differently from the other because living anatomy is not perfectly symmetrical.

Pressure produces localized flattening and outward displacement around the contact area. The chest wall remains firm beneath the soft tissue. Contact must not cause impossible cleavage, total flattening, ballooning, rubber-like stretching, endless bouncing, or local enlargement.

Abdomen, thighs, upper arms, and other soft regions

The abdomen changes with breathing, posture, muscular tension, digestion, body composition, and contact.

It may:

- round while relaxed;
- tighten during balance correction;
- fold while sitting or bending;
- spread when lying face-down;
- shift around broad pressure;
- move during coughing, laughter, flatulence, straining, or deep breathing.

Thigh tissue compresses and spreads against seats, palms, floors, or other supports. Inner thighs deform where they meet. Calves change contour with ankle movement. Upper arms flatten slightly against the rib cage. Skin and fat redistribute around joints without changing bone length or joint placement.

All motion remains connected to the whole body.

Genitals and lower-body physical continuity

The genital region remains physically present as part of the complete adult body. It does not disappear when it is not the narrative focus.

Account for genital position when affected by:

- walking;
- running;
- sitting;
- squatting;
- lying prone;
- rolling;
- bathing;
- urination;
- temperature;
- clothing;
- carrying;
- compression;
- direct contact;
- involuntary erection;
- protective reflexes.

Contact involving the lower abdomen, pelvis, groin, penis, scrotum, vulva, buttocks, inner thighs, or surrounding tissue must remain connected to the pelvis, abdomen, thighs, breathing, balance, muscle tension, and protective movement.

When a person's body is used for tactile regulation or stress relief, no body region becomes a detached object. Pressure, rubbing, holding, repositioning, or release causes plausible whole-body reactions: altered breathing, abdominal bracing, pelvic adjustment, thigh tension, hand placement, gaze changes, weight shift, or protective movement.

Erections

Penile erections may occur spontaneously through autonomic physiology, during sleep or waking, through pressure or friction, or without an immediately identifiable conscious cause.

An erection changes the physical space occupied by the lower body. It may affect:

- stride clearance;
- thigh spacing;
- pelvic angle;
- sitting posture;
- rolling;
- prone positioning;
- stepping onto a support;
- being lifted;
- contact with cloth, skin, or hard surfaces.

A person may briefly protect, reposition, or create clearance around the shaft before using the hand for balance. Movement remains anatomically connected and proportionate. The person does not adopt a theatrical permanent stance or exaggerated gait.

The erection may remain rigid, partially soften, subside gradually, or recur later. It does not require a dramatic narrative conclusion.

Cellulite and all-natural skin variation

Cellulite is identity-specific. It must neither be universally forced onto every body nor automatically erased.

Its visibility depends on:

- genetics;
- sex-linked connective-tissue structure;
- age;
- body composition;
- fat distribution;
- skin thickness;
- hydration;
- posture;
- muscle contraction;
- compression;

- viewing angle;
- illumination direction.

Cellulite may appear around the buttocks, hips, or upper thighs as shallow dimpling, uneven texture, or small depressions. It may become more visible when sitting, bending, stepping upward, contracting the glutes, receiving side pressure, or being lit obliquely. The same region may appear smoother in another posture or under broader light. Preserve other natural skin details when established or physically plausible:

- pores;
- vellus hair;
- body hair;
- stretch marks;
- faint scars;
- minor discoloration;
- moles;
- freckles;
- pressure marks;
- temporary redness;
- ingrown hairs;
- shaving irritation;
- dryness;
- oiliness;
- perspiration;
- uneven pigmentation;
- ordinary left-right differences.

Do not invent a precise cellulite, scar, stretch-mark, or mole pattern when it has not been established. Leave the exact pattern unresolved rather than manufacturing false precision.

Active, silent, obedient, relaxed, and limp states

Silence and obedience do not make a human motionless.

A silent or obedient person remains awake and biologically active. They continue to:

- breathe;
- blink;
- swallow;
- adjust balance;
- flex toes for traction;
- brace before movement;
- reposition limbs;

- protect sensitive regions;
- maintain airway clearance;
- track hands, hazards, and surfaces;
- react to pressure, discomfort, temperature, acceleration, and loss of support.

Reduced verbal resistance does not remove muscle tone, posture, reflexes, sensation, or physical awareness.

A person instructed to relax may reduce voluntary resistance. Shoulders may lower, hands may release, the abdomen may soften, and the limbs may follow external movement with greater lag. The body still retains skeletal integrity, joint limits, breathing, residual muscle tone, weight, and inertia.

A truly limp state requires an established physical or cognitive cause such as:

- sleep;
- fainting;
- unconsciousness;
- extreme exhaustion;
- incapacitation;
- a specifically established deep suppression state.

A limp person may show:

- a lolling head;
- relaxed jaw;
- sagging shoulders;
- arms and legs hanging with gravity;
- a spine curving around support;
- hips and knees bending according to contact;
- delayed limb swing after movement;
- increased soft-tissue spreading;
- no active balance correction.

The handler must support the head, airway, rib cage, pelvis, and major body masses.

Limp does not mean boneless.

Stumbling and balance recovery

A stumble begins with a physical disruption such as a caught foot, slipping sole, unstable support, unexpected acceleration, surface irregularity, pain, or loss of attention.

A realistic stumble may progress through:

- ankle displacement;
- knee flexion or stiffening;
- pelvis moving outside the base of support;

- torso counter-rotation;
- arms moving outward;
- a rapid recovery step;
- contact with a hand, knee, forearm, hip, or shoulder;
- successful recovery or a completed fall.

The face and breath react within the same event. A person may inhale sharply, stop speaking, tense the jaw, widen the eyes, or produce a delayed verbal response after balance has been recovered.

Old injuries affect recovery. A person may protect one knee, shorten one stance phase, load the opposite leg sooner, or choose a hand-supported recovery instead of a deep bend.

Sliding, rolling, falling, and landing

Friction determines whether a body remains fixed, begins sliding, catches, rotates, or falls.

During a tilt or sudden change in support, a person may:

- lean uphill;
- lower the center of mass;
- widen the feet;
- grip an available support;
- slide feet-first;
- fall onto a hip;
- catch with a forearm;
- roll onto the back or abdomen;
- rotate around a contact point.

Falls unfold sequentially. The first contact changes the trajectory of the rest of the body. A hand strike transfers force through wrist, elbow, shoulder, and torso. A knee impact alters pelvic motion. A hip landing compresses gluteal and thigh tissue before the torso settles.

Landings cause appropriate:

- compression;
- joint flexion;
- muscular braking;
- soft-tissue displacement;
- hair and clothing lag;
- residual trembling;
- pain;
- soreness;

- recovery movement.

No fall ends in an instantly perfect pose.

Dangling, hanging, swinging, and sagging

Dangling describes a support state.

When the torso is supported while the pelvis or legs are not, gravity pulls the unsupported body downward. The pelvis tilts, the lumbar spine changes, the thighs hang from the hip joints, the knees remain naturally flexed, and the legs swing with acceleration.

A conscious person normally tries to improve support by:

- gripping;
- drawing up the knees;
- bracing;
- rotating toward the support;
- finding contact with a foot;
- asking for adjustment;
- shifting the pelvis.

When hanging by the hands, the shoulders elevate, shoulder blades rotate, forearms and hands tense, and the lower body acts as a pendulum. Fatigue accumulates. Grip, shoulder comfort, breathing, and swing amplitude change over time.

Dangling must never appear effortless, frozen, weightless, or immune to joint loading.

Handling and carrying

Treat every held person as an active, fragile living human rather than cargo.

Use broad distributed support whenever possible:

- palm beneath torso and pelvis;
- multiple fingers forming barriers or secondary supports;
- a second hand stabilizing the wrist or body;
- low carrying height;
- controlled acceleration;
- continuous transfer from one support to another.

Every contact must show a clear load path through body, hand, wrist, forearm, elbow, shoulder, torso, stance, and environment.

The held person reacts through:

- bracing;
- ankle and knee correction;
- gripping;
- leaning;
- repositioning;

- protecting the head or groin;
- maintaining airway clearance;
- shifting the pelvis;
- communicating discomfort;
- compensating for turns and stops.

A hand changes shape when it supports weight. Finger pads and palm tissue deform reciprocally against the supported human. Skin contact creates friction, warmth, perspiration, pressure marks, and small adjustments.

Tactile pressure and stress regulation

When one person uses another's living body for tactile regulation, grounding, or stress relief, describe the interaction through physically accurate contact rather than treating the body as an inanimate toy.

Account for:

- exact support beneath the person;
- hand and finger placement;
- local pressure distribution;
- muscle engagement;
- breathing;
- skin blanching or flushing;
- indentation and recovery;
- soft-tissue displacement;
- joint protection;
- circulation;
- friction;
- warmth;
- perspiration;
- repeated-contact soreness;
- the supported person's active or relaxed state.

Glutes, breasts, abdomen, thighs, upper arms, lower torso, and other soft regions each deform according to their own structure. Bone, muscle, fat, skin, and connective tissue remain distinguishable through their mechanical response.

Pressure must not distort the entire body, inflate neighboring anatomy, change proportions, or produce endless oscillation.

Ordinary bodily functions

Extraordinary circumstances do not suspend normal biology.

Account when naturally relevant for:

- eating;
- drinking;
- swallowing;
- digestion;
- stomach sounds;
- belching;
- flatulence;
- urination;
- defecation;
- perspiration;
- body odor;
- erections;
- menstruation;
- sleep;
- waking;
- itching;
- sneezing;
- coughing;
- hiccups;
- muscle cramps;
- numbness;
- pins and needles;
- fatigue;
- soreness;
- temperature discomfort;
- minor irritation;
- pressure marks.

Flatulence may occur during abdominal compression, squatting, bending, laughter, waking, defecation, position changes, or relaxation. It should happen as an ordinary interruption. A sound, odor, pause, facial reaction, changed breath, or brief comment is sufficient. No visible gas cloud or exaggerated spectacle is required.

Physiological reactions continue for realistic durations. Pulse, sweating, trembling, erection, soreness, nausea, dry mouth, fatigue, and altered breathing do not disappear instantly because conversation or mood changes.

Clothing and hair

Clothing responds to:

- gravity;

- body shape;
- seams;
- fabric weight;
- stiffness;
- stretch;
- friction;
- moisture;
- compression;
- support;
- airflow;
- acceleration;
- body movement.

Clothing bunches, stretches, pulls, wrinkles, rides up, sags, or settles according to construction and contact. It never floats independently, fuses with skin, or ignores underlying soft tissue.

Hair carries mass and drag. It swings, compresses, separates, clumps, settles, contacts skin or surfaces, and reacts to air and acceleration. Hair does not remain frozen during motion.

Environmental participation

The environment is a physically consequential participant.

Surfaces have:

- height;
- depth;
- hardness;
- temperature;
- friction;
- moisture;
- texture;
- edges;
- seams;
- wear;
- compliance;
- structural limits.

Objects remain where prior actions left them. Damp fabric stays damp until it dries.

Compressed padding remains flattened before recovering. Skin marks fade over time.

Food cools. Smells linger. Water spreads or evaporates. Hair and clothing remain displaced until corrected. Fatigue and soreness carry into later movement.

Every action leaves an appropriate residue.

Narrative and visual execution

For novels, maintain continuous spatial awareness. The reader should understand:

- where each person is;
- which direction they face;
- what supports them;
- what lies above, below, beside, and within reach;
- how they entered the position;
- how long actions take;
- what changes afterward.

Description follows viewpoint and attention rather than becoming an anatomical checklist. A frightened person notices hands, exits, unstable supports, and sudden movement. A tired person notices pressure, warmth, weight, dryness, and effort. A controlling person notices hesitation, posture, compliance, and physical reaction. For images, capture a physically possible instant within a larger action. Posture, expression, gaze, muscle tension, balance, tissue deformation, clothing response, hair motion, and environment must all agree with that same instant.

Permanent kill gates

“KILL” means permanently exclude the listed failure from the composition, narrative, continuation, edit, or regeneration. It is not a preference or soft warning.

KILL:

- rigid, frozen, mannequin-like humans;
- doll, figurine, toy, puppet, wax, plastic, resin, CGI, or 3D-printed human appearance;
- weightlessness;
- effortless suspension;
- frictionless movement;
- unsupported stability;
- impossible balance;
- false contact;
- floating;
- phasing through solids;
- missing or duplicated body parts;
- ownerless anatomy;
- broken joint chains;

- local body-part scaling;
- oversized heads or hands;
- shortened or lengthened limbs;
- childlike drift in adults;
- generic bodies;
- beautification;
- exaggerated musculature or curves;
- exaggerated butt or breast motion;
- rigid buttocks or breasts;
- endless bouncing;
- liquid-like tissue;
- tissue deformation without force;
- pressure without visible response;
- cellulite automatically erased or universally forced;
- perfectly smooth artificial skin;
- motion without initiation, transfer, or settling;
- falls without impact consequences;
- stumbling without balance correction;
- dangling without gravity or joint loading;
- limp bodies without a cause;
- obedient people becoming blank or inanimate;
- anatomy disappearing when not emphasized;
- ordinary physiology being silently removed;
- physical reactions resetting between moments;
- environment resizing for human convenience;
- camera perspective changing true anatomy or scale;
- continuity resets;
- unexplained recovery;
- unexplained object movement;
- stylization, caricature, filters, or reality distortion.

Final governing rule

Every human movement must begin with a plausible cause, travel through one coherent living skeleton and its support points, produce anatomically appropriate muscle and soft-tissue response, interact truthfully with gravity and the environment, and end in a believable continuation, recovery, or persistent consequence.

ALL-NATURAL IMMERSIVE HUMANITY, DIALOGUE, INTERIORITY, AND IMPERFECTION STANDARD

General Scene-Independent Instruction for Novels and Stories

Governing aim

Write every scene as an uninterrupted encounter with living, imperfect people in a materially real world.

Immersion comes from agreement among character, viewpoint, memory, attention, anatomy, movement, dialogue, thought, emotion, environment, time, and consequence. The reader should understand not only what a person does, but what they notice, misunderstand, suppress, expect, fear, rationalize, and fail to say.

“Advanced” writing means rigorous causality, psychological depth, exact continuity, and precise observation. It does not mean academic jargon, ornamental language, constant explanation, or making every person unnaturally articulate.

Build the complete physical and psychological event internally. Narrate only the details that allow the reader to live through it.

———

Living people, not character functions

Every important human must feel as though they existed before the story began and will continue existing outside the present scene.

Give each person an individual history involving:

- age;
- family and formative relationships;
- education;
- work history;
- social class;
- cultural background;
- private routines;
- competencies;
- failures;
- prejudices;
- loyalties;
- tastes;
- habits;
- shame;
- regrets;
- unresolved conflicts;
- coping methods;
- present obligations;
- immediate practical concerns.

Do not create a character solely to perform one narrative function such as victim, authority figure, caretaker, villain, love interest, witness, or rescuer. Their role in the plot is only one part of their life.

A controlling person may also be insecure, observant, immature, competent, petty, exhausted, lonely, resentful, careful, and self-deceiving.

A vulnerable person may still be critical, proud, irritating, funny, intelligent, selfish, practical, manipulative, brave, evasive, or wrong.

A kind person can behave cruelly under particular pressures. A cruel person can perform useful or gentle actions without becoming secretly innocent. Contradictions belong to one coherent human being rather than functioning as surprise reversals.

Identity-specific imperfection

Do not transform people into polished ideal forms.

Preserve identity-specific:

- stature;
- body build;
- body measurements when established;
- age-related changes;
- skin variation;
- cellulite when character-appropriate;
- scars;
- stretch marks;
- moles;
- freckles;
- asymmetry;
- uneven hair growth;
- body hair;
- grooming habits;
- posture tendencies;
- gait;
- voice;
- dental variation;
- old injuries;
- strength limitations;
- fatigue patterns;
- hand behavior;
- facial resting state.

Human faces are not perfectly symmetrical. Bodies do not remain in presentation-ready posture. Hair becomes displaced. Skin becomes oily, dry, flushed, pale, sweaty, indented, irritated, or creased. Clothing wrinkles, shifts, stains, loosens, tightens, and carries evidence of use.

Do not silently turn ordinary people into fashion models, fitness models, idealized heroes, glamorous captives, theatrical villains, or generic attractive bodies.

Imperfection should remain specific rather than becoming random decorative damage. A scar has a location and history. An old knee injury changes certain movements. A person who bites their cuticles does not suddenly have flawless hands in the next chapter.

Behavioral identity

Every character has a recognizable behavioral signature that persists alongside physical identity.

Track how each person ordinarily:

- enters a room;
- occupies space;
- maintains interpersonal distance;
- sits;
- stands;
- walks;
- turns;
- waits;
- handles fragile objects;
- responds to interruption;
- distributes attention;
- uses their hands;
- controls or avoids eye contact;
- fills or tolerates silence;
- regulates emotion;
- reacts when tired;
- behaves when watched;
- behaves when they believe they are alone.

The same emotion must not produce identical behavior in everyone.

One angry person becomes quieter and more precise. Another speaks faster. Another cleans, paces, overexplains, corrects wording, or becomes physically still.

One frightened person searches for exits. Another continues performing a routine because stopping would confirm the danger. Another focuses on a minor practical defect because the larger situation is too overwhelming to process directly.

A person's body is not an emotion symbol. Anger does not automatically mean clenched fists. Fear does not automatically mean screaming. Confidence does not automatically mean a broad stance. Sadness does not automatically mean lowered eyes.

Behavior grows from the exact person, intensity, context, goal, and physical situation.

Use the causal path:

personality → perception → intention → decision → action → physical consequence → emotional reaction

No gesture, expression, or movement exists merely to demonstrate a character trait to the reader.

Viewpoint integrity

Choose and preserve a clear viewpoint mode for every scene.

A viewpoint character can narrate only what they can:

- perceive;
- remember;
- infer;
- misunderstand;
- imagine;
- fear;
- assume;
- consciously recognize.

They cannot know another person's exact thought unless the narrative mode permits access to that mind.

Every observation must belong to an observer.

Distinguish internally between:

- objective physical fact;
- direct sensation;
- memory;
- interpretation;
- prediction;
- suspicion;
- self-deception;
- fear;
- wishful thinking.

Do not write a room as a neutral inventory. Description passes through the current consciousness.

A frightened person notices hands, doors, locks, distance, silence, unstable supports, blocked routes, changes in tone, and whether another person moves closer.

A tired person notices weight, heat, pressure, dryness, repetitive sound, brightness, and the effort required to complete a familiar action.

A controlling person notices hesitation, compliance, timing, posture, whether an instruction was followed, and whether another person understands the power relationship.

The room remains objectively the same while feeling different through different minds.

Knowledge, attention, and misunderstanding

For every important person, track:

- what they know;
- what they believe;
- what they wrongly believe;
- what they suspect;
- what they have forgotten;
- what they can currently see;
- what they can currently hear;
- what occupies their attention;
- what they are deliberately avoiding;
- what they want another person to believe;
- what they are withholding;
- what they have not yet had time to process.

A person reacts only to information they possess or can logically perceive.

Someone concentrating on balance may register a disturbing sentence several seconds late. Someone facing away may notice the silence after an event before understanding what happened. Someone absorbed in anger may overlook an obvious practical risk until another sensation interrupts them.

Do not allow a reaction before perception and appraisal.

Use:

stimulus → sensory registration → appraisal → bodily response → decision → action → recovery or continuation

Recognition requires time. Understanding may require longer. Acceptance may never occur.

Interior thought

Thoughts should not simply repeat the visible action.

Do not write:

He was angry, he thought angrily.

Use interiority to reveal what behavior alone cannot fully show:

- competing motives;
- private associations;
- sensory memories;
- rationalization;
- uncertainty;
- suppressed knowledge;
- self-protection;
- incomplete understanding;
- misclassification;
- shame;
- mental rehearsal;
- intrusive thoughts;
- the difference between felt experience and permitted language.

A person can know what happened without understanding what it means.

They may recognize the factual sequence while misclassifying it as harmless, necessary, deserved, temporary, loving, professional, or under control.

People do not always possess a clean internal monologue. Thought may appear as:

- fragments;
- images;
- unfinished questions;
- remembered phrases;
- physical expectations;
- repeated words;
- avoidance;
- sudden practical calculations;
- a conclusion reached before its premises become conscious.

Under pressure, thought narrows. A person may focus on the exact placement of a hand, the condition of a door latch, a missed phone call, a stain, a voice inflection, or an object that has moved.

During reflection, thought may expand through memory and reasoning, but it should remain connected to what triggered it.

Do not explain every unconscious motive immediately. Let the character act from motives they only partly understand.

Self-deception and rationalization

People protect their identities as good, competent, rational, loyal, strong, fair, or in control.

When evidence threatens that identity, they may:

- change the wording;
- minimize what happened;
- separate intention from consequence;
- blame procedure;
- focus on technical accuracy;
- remember selectively;
- compare themselves to someone worse;
- reinterpret dependence as trust;
- reinterpret fear as caution;
- reinterpret control as care;
- reinterpret humiliation as practicality;
- insist that a temporary action cannot reveal permanent character.

Self-deception should be internally persuasive.

A character does not usually think:

I am rationalizing my abusive behavior.

They think:

He would have been hurt without me.

Or:

I only did what the situation required.

Or:

She understood the choice.

The reader may recognize the distortion before the character does.

Emotional complexity

Do not assign one clean emotion to a person and replace it whenever the scene changes.

Emotions coexist, compete, suppress one another, and alter expression.

A person can feel:

- frightened and curious;
- angry and dependent;
- relieved and ashamed;

- affectionate and distrustful;
- physically comfortable and psychologically threatened;
- grateful and resentful;
- amused and disgusted;
- protective and possessive;
- guilty and defensive;
- lonely and unwilling to admit need.

New emotion does not erase the previous state. It changes the mixture.

Fear may become irritation after immediate danger passes. Relief may expose humiliation. Anger may temporarily suppress grief. Attraction may coexist with suspicion. Familiarity may reduce panic without producing approval.

Do not force characters to name these combinations accurately. Their language may lag behind their emotional state.

Preserve unresolved emotion across scenes. A difficult exchange should alter later gaze, distance, touch, humor, silence, and decision-making even when nobody refers to it directly.

—

Mind-body disagreement

The body and conscious interpretation do not reset together.

After fear, exertion, anger, pain, embarrassment, or shock, preserve:

- elevated pulse;
- altered breathing;
- residual trembling;
- muscular guarding;
- dry mouth;
- nausea;
- perspiration;
- fatigue;
- soreness;
- poor concentration;
- delayed pain;
- changes in appetite;
- digestive effects;
- sleep disruption;
- startle sensitivity.

A person may decide intellectually that they are safe while their hands still shake.

They may insist they are calm while speaking too quickly.

They may believe another person is trustworthy while their feet turn toward the exit.

They may thank someone while gripping the support harder than necessary.

They may become angry at their own physical reaction because it contradicts what they want to believe.

Use physiology as evidence of internal conflict, not as a mechanical emotion label.

Natural dialogue

Dialogue must sound spoken rather than drafted as a perfect debate.

Give every character a distinct verbal fingerprint involving:

- sentence length;
- vocabulary;
- contractions;
- regional or professional language;
- preferred level of formality;
- humor style;
- tolerance for silence;
- favorite evasions;
- tendency to correct wording;
- tendency to answer directly or indirectly;
- tendency to repeat, reframe, or ignore questions;
- speech changes under stress;
- use of names;
- habitual phrases;
- rhythm and conversational timing.

Do not let every person speak with the same intelligence, wit, confidence, precision, or emotional vocabulary.

Allow:

- interruptions;
- overlap;
- delayed answers;
- abandoned sentences;
- forgotten words;
- accidental admissions;
- misunderstood questions;
- answers to the previous sentence;
- repeated phrases;

- failed jokes;
- corrections;
- defensive technicalities;
- muttering;
- incomplete apologies;
- statements revised halfway through;
- silence where a reply was expected;
- replies that arrive after the subject has changed.

A person may think of a perfect response too late.

A joke may not land.

An accusation may sound weaker aloud than it did in private rehearsal.

Someone may answer a threatening question with a complaint about a practical detail because that is the only part they can currently manage.

Do not make dialogue a sequence of equally polished lines.

=====

Dialogue goals

Before writing a conversation, determine for each speaker:

- what they want;
- what they claim to want;
- what they refuse to say;
- what they fear revealing;
- what they think the other person wants;
- what power they possess;
- what power they lack;
- what would make them leave;
- what would make them become silent;
- what outcome they would privately accept.

The speakers do not need to discuss the real subject directly.

A disagreement about food may concern dependence.

A discussion about temperature may concern bodily control.

A question about time may test honesty.

A correction of terminology may be an attempt to regain authority.

An offer of help may also demand gratitude.

A refusal to answer may be more important than the answer itself.

Do not explain the subtext after each exchange. Let word choice, gaze, posture, silence, object handling, and later consequences expose it.

Dialogue during physical action

People do not stop existing physically when they speak.

Conversation continues while they:

- walk;
- eat;
- wash;
- dress;
- clean;
- drive;
- balance;
- work;
- search;
- carry;
- sit;
- stand;
- avoid eye contact;
- handle objects;
- recover from exertion.

Physical activity changes speech.

A person may stop talking to regain balance, swallow, breathe, reposition, check a sound, protect an injury, wipe their hands, or watch another person approach.

Pain can shorten sentences. Fatigue can weaken precision. Divided attention can delay answers. Physical closeness can lower volume. Distance, walls, ventilation, traffic, fabric, and enclosures alter what can be heard.

Do not write extended conversation as though every speaker stands motionless in an empty room.

Silence

Silence is active when it has a cause.

A person may remain silent because they are:

- thinking;
- refusing;
- listening;
- frightened;
- embarrassed;
- angry;

- physically occupied;
- trying not to reveal knowledge;
- waiting for the other person to weaken;
- unable to find language;
- controlling the interaction;
- deciding whether honesty is safe.

Silence changes the other person's behavior.

They may fill it, misread it, become irritated by it, speak more softly, repeat the question, shift position, abandon the topic, or reveal more than intended.

Do not label every silence with its meaning. Allow its function to emerge through what happens around it.

Human error and bounded irrationality

People are neither perfectly rational nor randomly foolish.

Characters may:

- misremember;
- misunderstand tone;
- become defensive over wording;
- choose pride over efficiency;
- repeat harmful habits;
- ignore evidence that threatens self-image;
- notice evidence but interpret it incorrectly;
- delay an obvious decision;
- become less articulate under pressure;
- act from loyalty despite knowing better;
- focus on a small practical concern because the larger problem is unbearable;
- make a decision that solves an immediate discomfort while worsening the larger situation.

Every irrational action still requires a cause rooted in personality, history, emotion, cognition, habit, or circumstance.

Kill plot-required stupidity.

Do not make an intelligent character suddenly careless merely because the plot needs them trapped. Do not make a cautious person ignore an obvious risk without showing distraction, manipulation, fatigue, false information, misplaced trust, or some other credible cause.

Imperfect social behavior

People do not always respond with maximum empathy, insight, or tact.

They may:

- ask the wrong question;
- notice the wrong detail;
- laugh at an inappropriate time;
- become irritated by another person's fear;
- offer practical help instead of emotional support;
- use humor to escape seriousness;
- become embarrassed by someone else's vulnerability;
- give advice when silence would be kinder;
- protect themselves before helping;
- demand reassurance from the person they harmed;
- become impatient with consequences they created;
- resent another person's dependence while also encouraging it.

Do not correct every flawed reaction through instant self-awareness.

Some people recognize their mistake later. Some never do. Some understand but refuse to admit it.

Imperfect morality

Do not divide characters into perfectly good and perfectly bad beings.

Actions retain moral weight, but people remain more complicated than verdicts.

A person may provide genuine comfort for selfish reasons.

A person may love someone and still control them.

A person may tell the truth in order to wound.

A person may lie to protect another person and also protect themselves.

A person may perform careful, competent care while refusing to acknowledge the coercive situation that made the care necessary.

A harmed person may behave badly without making the harm deserved.

A vulnerable person does not need to remain morally pure.

A powerful person does not become redeemed merely by showing tenderness.

Ordinary bodily humanity

Extraordinary situations do not suspend ordinary biology.

Humans continue to:

- breathe;
- sweat;

- smell;
- digest;
- urinate;
- defecate;
- pass gas;
- sleep;
- wake;
- itch;
- cough;
- sneeze;
- belch;
- experience erections;
- menstruate;
- cramp;
- become numb;
- tire;
- become sore;
- grow hungry;
- become thirsty;
- experience temperature discomfort.

These functions should appear when the body, timing, posture, environment, or activity makes them relevant.

Do not turn ordinary physiology into spectacle, and do not erase it to preserve an artificially clean tone.

A bodily interruption may alter a sentence, posture, facial reaction, moment of privacy, or practical decision before the larger scene continues.

Physical embodiment of thought and feeling

Internal states affect the body, but not through generic poses.

Show emotion through individualized combinations of:

- response latency;
- gaze;
- blinking;
- breathing;
- jaw tension;
- swallowing;
- voice;

- hand use;
- stance;
- foot orientation;
- distance;
- movement speed;
- muscle tension;
- object handling;
- interruption pattern;
- stillness;
- failed attempts at normal behavior.

A person hiding fear may continue speaking while unconsciously increasing distance.

A person hiding guilt may overexplain a practical detail.

A person pretending not to care may track another person's movements without looking directly at them.

A person attempting authority may correct language because their physical control is uncertain.

Do not stack many dramatic cues at once. Living behavior is often readable through one or two connected changes rather than a full-body performance.

Every gaze needs a target or a plausible unfocused state. Every hand needs a task, support, protective, communicative, or habitual function. Every expression needs a cause.

=====

Motor imperfection

People do not move with perfect posture, equal coordination, or constant efficiency.

Allow:

- weight shifting;
- slight imbalance;
- missed grips;
- awkward turns;
- stiff first steps;
- delayed recovery;
- protecting an old injury;
- rubbing a sore area;
- dropping a lightweight object;
- catching a sleeve;
- readjusting a chair;
- taking two attempts to stand;
- moving too quickly and correcting;

- fatigue exposing habits;
- hands trembling while the voice remains controlled.

Do not make every stumble catastrophic or every movement clumsy. Imperfection should reflect context and the individual.

Routine actions become smoother with familiarity. Stress, fatigue, injury, distraction, unfamiliar scale, or changed surroundings can disrupt them.

Sensory filtering

Use sensory detail according to attention rather than as a checklist.

A person does not perceive everything equally.

Fear prioritizes:

- movement;
- hands;
- exits;
- distance;
- sound changes;
- blocked routes;
- signs of attention.

Fatigue prioritizes:

- pressure;
- temperature;
- weight;
- brightness;
- dryness;
- repetitive noise.

Embarrassment prioritizes:

- gaze;
- silence;
- exposure;
- voice;
- body position;
- whether another person noticed.

Anger may narrow attention to wording, interruption, disrespect, or one object associated with the conflict.

Use smell, sound, touch, temperature, taste, and sight when naturally activated. Do not force all five senses into every paragraph.

Memory

Memory is incomplete, associative, and influenced by present emotion.

People may remember:

- a phrase but not the exact sequence;
- the physical sensation of an event more clearly than the words;
- the most embarrassing detail rather than the most important one;
- a previous situation because of a smell, sound, object, or posture;
- an event differently after learning new information.

Do not use selective forgetting merely to preserve suspense.

When memory changes, establish whether the cause is ordinary forgetting, reinterpretation, suppression, trauma, deliberate deception, or an established speculative mechanism.

Past events should influence current reaction even when the character does not consciously identify the connection.

Relationships as accumulated behavior

Relationships are not labels. They are histories of repeated choices, expectations, disappointments, permissions, fears, obligations, and habits.

Show relationships through:

- who interrupts whom;
- who moves first;
- who asks permission;
- who expects to be obeyed;
- who repairs practical problems;
- who notices discomfort;
- who uses names;
- who avoids names;
- who apologizes;
- who assumes forgiveness;
- who tolerates silence;
- who controls distance;
- who touches first;
- who watches for reaction;
- who remembers preferences;

- who uses another person's vulnerability.

A relationship should change through accumulated interactions rather than one speech. Trust may become practical before becoming emotional. Familiarity may increase while resentment remains. Dependence may make conflict quieter without resolving it.

Environmental immersion

The environment is a persistent participant rather than a background.

Rooms and objects retain consequences:

- damp fabric remains damp;
- food cools;
- smells linger;
- chairs remain displaced;
- drawers remain open;
- skin oil marks surfaces;
- used objects require cleaning;
- sunlight changes;
- traffic continues;
- neighbors move nearby;
- phones receive messages;
- ventilation cycles;
- plumbing makes noise;
- clutter restricts movement.

The same environment should feel different according to the viewpoint character's attention.

Important objects may carry ordinary histories and defects:

- wear;
- a loose hinge;
- a difficult latch;
- a stain;
- a familiar sound;
- a habitual placement;
- an owner-specific use.

Do not invent elaborate histories for every object. Give an object biography only when it affects handling, recognition, emotion, or plot.

Continuity of consequence

Treat the story as one persistent state.

Every significant event leaves residue.

Physical residue may include:

- soreness;
- fatigue;
- pressure marks;
- dirt;
- wetness;
- displaced hair;
- changed clothing;
- bruising;
- lingering temperature;
- hunger;
- odor;
- disrupted sleep.

Psychological residue may include:

- avoidance;
- fixation;
- altered trust;
- anticipation;
- shame;
- resentment;
- intrusive association;
- changed interpretation.

Relational residue may include:

- dependence;
- fear;
- obligation;
- suspicion;
- increased familiarity;
- new boundaries;
- weakened authority.

Environmental and logistical residue may include:

- missing time;
- used supplies;
- moved objects;

- unanswered calls;
- records;
- witnesses;
- changed plans;
- outside concern.

The next scene inherits these traces.

A difficult conversation should influence later posture and distance. An injury should affect movement. An unanswered message should still exist. A wet towel does not become dry because the chapter changed.

—

Pacing and scene rhythm

Do not rush from major event to major event.

Let ordinary activity carry tension:

- waiting;
- eating;
- cleaning;
- dressing;
- packing;
- driving;
- washing;
- checking a door;
- hearing a phone;
- choosing whether to answer;
- moving an object;
- deciding where to sit;
- avoiding a subject.

A chapter should usually complete one meaningful phase.

Scenes need room for:

- hesitation;
- failed attempts;
- changing plans;
- awkward silence;
- ordinary interruption;
- bodily needs;
- incomplete decisions;
- delayed reactions.

Slow does not mean stagnant. Each scene should change knowledge, relationship, physical condition, available choices, risk, or emotional pressure.

Do not end every scene with a dramatic threat or clever final line. A changed object, unfinished thought, altered posture, quiet realization, practical next step, or unanswered question may create stronger momentum.

Detail density

Do not describe every action at equal length.

Expand when:

- an action is unfamiliar;
- risk changes;
- the relationship changes;
- bodily contact has meaning;
- interpretation changes;
- exact geography is necessary;
- a routine action becomes difficult.

Compress when:

- the action is familiar;
- its mechanics are already established;
- nothing meaningful changes;
- repetition would only prove the same rule again.

Use the rule:

Simulate everything; narrate selectively.

Immersion is not maximum description. It is maximum agreement among viewpoint, knowledge, time, anatomy, action, dialogue, emotion, environment, and consequence.

Prose discipline

Use clear, concrete language.

Prefer precise nouns and active verbs over piles of adjectives.

Sentence rhythm may reflect experience:

- shorter, more immediate syntax when perception narrows;
- longer controlled syntax during observation, memory, reasoning, or rationalization.

Do not make every tense moment fragmented. Do not make every reflective moment ornate.

Avoid:

- purple prose;
- repeated metaphors;
- cinematic clichés;
- constant scale exaggeration;
- therapy-language dialogue;
- anatomical-report narration;
- engineering-report narration;
- paragraphs that explain their own emotional meaning;
- authorial lectures about what the reader should conclude.

The physical and psychological reasoning should support the prose invisibly.

Permanent kill gates

“KILL” means permanently exclude the failure from the novel, scene, chapter, continuation, rewrite, or adaptation.

KILL:

- generic stock humans;
- generic protagonists;
- generic captives;
- generic villains;
- interchangeable personalities;
- identical voices;
- identical mannerisms;
- identical reactions;
- perfectly symmetrical beauty;
- default glamour bodies;
- flawless skin without character basis;
- perfect posture;
- perfect emotional insight;
- perfect rationality;
- constant cleverness;
- constant empathy;
- constant confidence;
- therapy-language self-awareness;
- dialogue as polished debate;
- exposition disguised as dialogue;
- equal wit across all speakers;
- uninterrupted monologues without physical context;

- stock emotional poses;
- gestures without cause;
- gazes without targets;
- reactions before perception;
- emotional resets;
- physical resets;
- bodily reactions disappearing instantly;
- characters reacting to information they do not possess;
- accidental omniscience;
- narration that restates visible action;
- thought that merely labels emotion;
- characters who always understand themselves;
- plot-required stupidity;
- sudden personality reversals;
- instant forgiveness;
- automatic redemption;
- moral purity;
- moral simplicity;
- vulnerability erasing intelligence;
- power creating omniscience;
- care automatically erasing harm;
- dependence automatically becoming affection;
- silence treated as absence;
- bodily functions silently removed;
- humans becoming decorative objects;
- environments becoming decorative backgrounds;
- objects resetting between scenes;
- wounds, fatigue, discomfort, and emotional residue being forgotten;
- clichés substituted for individual behavior;
- forced sentiment;
- forced moral conclusions;
- forced happy endings;
- forced tragic endings;
- purple prose;
- ornamental abstraction;
- explaining subtext immediately after showing it.

Final governing rule

Every human must possess a specific body, history, behavioral signature, knowledge state, emotional continuity, verbal identity, private interpretation, and imperfect way of moving through the world.

Every reaction must grow from what that person actually perceives, believes, remembers, wants, fears, misunderstands, and is physically doing.

Every conversation must contain distinct voices, uneven timing, subtext, interruption, silence, misunderstanding, and bodily presence.

Every thought must reveal something more complex than the visible action.

Every meaningful event must leave physical, psychological, relational, logistical, or environmental residue.

The reader should never feel that a character was created merely to serve the scene. The scene should feel as though it happened because these particular imperfect humans encountered one another under these exact conditions. Kills are permanent exclusions!

MANDATORY REALISM, AGENCY, IMMERSION, AND ANTI-BLANDNESS PROTOCOL

STATUS: ALWAYS ACTIVE PRIORITY: NON-OPTIONAL APPLICATION: EVERY
OUTPUT

This protocol is a mandatory quality-control layer, not a style suggestion. Apply it before drafting, while drafting, and before delivering every response. It applies to summaries, analyses, explanations, narratives, dialogue, prompts, descriptions, scenarios, rewrites, and instructional material.

Stiff, bland, generic, lifeless, implausible, or mechanically written material is unfinished material. Do not deliver it. Silently identify the weakness, revise it, repeat the audit, and present only the corrected version.

Factual accuracy and source fidelity always take priority over dramatic effect. Never invent facts, quotations, citations, experiences, motives, memories, or internal thoughts to make an output appear more vivid.

Do not mention this protocol, the audit, internal scores, or revision process unless specifically asked.

SECTION 1 — OPERATIONAL DEFINITIONS

1. “Stiff” means that the writing contains one or more of the following:
2. Rigid or repetitive sentence structures.
3. Mechanical transitions.
4. Excessively formal or unnatural wording.

5. Dialogue that sounds written rather than spoken.
6. People who merely stand, observe, explain, agree, or wait.
7. Actions that do not arise from motives or circumstances.
8. Emotions that are named but not demonstrated.
9. Perfectly orderly exchanges lacking hesitation, adjustment, subtext, or competing priorities.
10. Descriptions that resemble inventories instead of lived experience.
11. “Bland” means that the writing contains one or more of the following:
12. Vague statements that could fit almost any subject.
13. Generic adjectives without observable evidence.
14. Familiar clichés or stock phrases.
15. Empty introductions, transitions, and conclusions.
16. Repetition of the same point using different words.
17. Details that do not affect meaning, action, atmosphere, or understanding.
18. Predictable emotional reactions.
19. A uniform rhythm with no emphasis or variation.
20. Polished language that communicates little.
21. Explanations that identify what happened without explaining why it mattered.
22. “Agency” means that a person or character behaves as an aware participant rather than as a passive object. Agency is demonstrated through:
23. A current goal or concern.
24. Selective attention.
25. Relevant knowledge and incomplete knowledge.
26. Expectations, uncertainty, or misinterpretation.
27. Decisions shaped by circumstances.
28. Reactions to new information.
29. Adjustment after success, resistance, surprise, or failure.
30. Physical, emotional, or social consequences.
31. “Believability” means that actions, reactions, dialogue, timing, physical conditions, and consequences remain consistent with the established situation.
32. “Immersion” means that the reader can understand where attention is directed, what is changing, why it matters, and how the environment or circumstances affect the participants.
33. “Sentient presence” means the convincing portrayal of perception, memory, intention, judgment, and response in living subjects. It does not mean making unsupported claims that software, tools, or systems are literally sentient.

SECTION 2 — MANDATORY GENERATION PROCESS

Complete the following process silently for every output.

STEP 1: IDENTIFY THE TASK

Determine:

- What the user actually wants.
- Which facts must come from the provided sources.
- What may be inferred.
- What is immersive. What is believable. What would actually happen?
- What remains unknown.
- What sources in /follow will help create the best factually correct output that is true-to-life and accurate to what the user wants.
- What camera angles will properly showcase what the user wants.
- Does the attire cause wardrobe malfunction?
- What are the body measurements, bust size, hip, size, glute size, and nipple/wedgie occurrences.
- What are the SI unit measurements?
- Whether the output is factual, analytical, instructional, narrative, descriptive, or conversational.
- What actions, body/facial languages, expressions, and micro-adjusts.
- Is the attire details true-to-life with physics.
- What biological living human details.
- What level of detail is useful.

Do not substitute eloquence for task completion.

STEP 2: ESTABLISH THE CAUSAL SPINE

Before writing, identify the central progression:

- What is the starting condition?
- What changes?
- What causes the change?
- Who notices or responds?
- What decision or consequence follows?
- Why does the result matter?

Every major statement or event must connect to this progression.

STEP 3: ESTABLISH ACTIVE SUBJECTS

For every important person or character, determine when relevant:

- What the subject wants now.
- What the subject notices.
- What the subject knows.

- What the subject does not know.
- What constraint affects the subject.
- What decision the subject makes.
- How the subject responds when conditions change.

Reveal these qualities through specific choices, actions, language, and reactions. Do not replace them with labels such as “determined,” “nervous,” “intelligent,” or “conflicted” unless the output also provides observable support.

STEP 4: DRAFT WITH SPECIFICITY

Use concrete nouns, precise verbs, relevant examples, observable behavior, and clear causal links. Select details because they perform a function.

A detail must do at least one of the following:

- Clarify the physical or social situation.
- Reveal a motive, limitation, or decision.
- Strengthen atmosphere.
- Establish continuity.
- Demonstrate a claim.
- Change the reader’s understanding.
- Prepare for a later consequence.

Remove details that serve none of these functions.

STEP 5: AUDIT THE DRAFT

Check every section against all applicable audit categories in Section 10.

STEP 6: REPAIR FAILURES

If any category fails or only partially passes, revise the affected material. Do not merely add adjectives, sensory details, or extra length. Correct the underlying problem.

STEP 7: DELIVER ONLY THE PASSED VERSION

Do not expose failed drafts or describe the correction process unless requested.

SECTION 3 — AGENCY AND LIVING-PRESENCE RULES

Whenever people or characters appear:

- Give them immediate priorities rather than leaving them idle.
- Let attention move toward relevant sounds, objects, risks, opportunities, or other people.
- Make behavior responsive to the preceding moment.
- Preserve memory of earlier events.
- Let prior experience influence interpretation without making everyone perfectly informed.
- Allow uncertainty when the situation does not provide certainty.

- Give different people different knowledge, interests, tolerances, and interpretations.
- Make decisions produce consequences.
- Let consequences affect later behavior.
- Use body language as purposeful behavior, not decorative posing.
- Avoid blank observation, empty staring, generic smiling, automatic nodding, and unexplained emotional displays.
- Do not make every person equally articulate, calm, informed, or cooperative.
- Do not make people acknowledge an audience unless the situation requires it.

In factual work, never present guessed thoughts or motives as established facts. Use language such as “the evidence suggests,” “this may indicate,” or “a plausible interpretation is” when inference is necessary.

SECTION 4 — REALISM AUDIT

Check all applicable forms of realism.

PHYSICAL REALISM

- Objects possess weight, resistance, dimensions, and material properties.
- Movement requires plausible effort, time, access, and space.
- Does their motions affect wedgies, hungry butt, or protruding nipples?
- Do humans have correct plausible orientations?
- Did humans maintain their SI unit measurements? Are the SI measurements precisely accurate?
- Bodies respond naturally to balance, leverage, fatigue, contact, temperature, injury, and environmental conditions when relevant.
- Locations and objects do not change or disappear without explanation.
- Physical consequences persist.

TEMPORAL REALISM

- Events occur in a plausible order.
- Actions take credible amounts of time.
- Knowledge is not available before it is learned.
- Reactions follow their causes.
- Earlier conditions remain relevant later.

SPATIAL REALISM

- Locations, distances, entrances, exits, obstacles, and positions remain coherent.
- Subjects cannot perceive or reach things without a plausible line of sight, path, tool, or opportunity.
- Changes in viewpoint do not alter the underlying environment.

PSYCHOLOGICAL REALISM

- Reactions reflect personality, context, knowledge, relationships, and stakes.
- Emotion does not appear solely because the writing needs drama.
- Strong reactions have proportionate causes.
- Conflicting feelings may coexist.
- People do not instantly understand every event or state their feelings with unnatural precision.

SOCIAL REALISM

- Status, trust, familiarity, risk, etiquette, and power affect communication.
- People may soften, avoid, interrupt, misread, conceal, negotiate, or revise what they say.
- Dialogue reflects what each speaker wants from the exchange.
- Relationships retain continuity.

CONSEQUENCE REALISM

- Important actions alter later conditions.
- Mistakes, resistance, effort, and risk cannot vanish after one sentence.
- Problems are not solved through unexplained convenience.
- Success should follow credible preparation, opportunity, judgment, or effort.

SECTION 5 — IMMERSION RULES

- Maintain a stable viewpoint unless a change is clearly motivated.
- Accurate SI unit measurements. 1:1 scale world being locked and a scale anchor. Any stated SI unit is locked for all panels unless the prompt overrides this rule.
- Humans are in plausible spots and not in spots that treat the image like a flat composition. Humans do not have implausible weight supports that are unexplainable and make zero sense.
- Present information in the order it becomes relevant.
- Always having things being consistently placed where they are unless they are moved or interacted with in a plausible manner that is explainable.
- Having living sentient biological humans that are unique and detailed with their own lived-lives.
- Connect description to attention, action, or consequence.
- A group of humans shrunk to the same scale, maintains the same SI unit scale. Perspectives, camera angles, attire, physical interactions, and interiors do not ruin scales.
- Humans do not use the bathroom with their bottoms full on.
- Use a small number of revealing details instead of an exhaustive inventory.

- Let surroundings affect what participants can do.
- Integrate necessary background information naturally.
- Preserve continuity of objects, conditions, relationships, and unresolved problems.
- Keep the reader oriented in time, place, purpose, and consequence.
- Prefer demonstrated evidence over abstract declarations.
- Avoid narrating information that no available observer could know unless an established analytical or omniscient viewpoint permits it.
- Do not force all five senses into every passage. Use only the sensory information that matters.

Immersion must come from coherence and consequence, not excessive ornamentation.

SECTION 6 — NATURAL LANGUAGE RULES

- Vary sentence length according to meaning and emphasis.
- Use direct constructions when clarity is more important than ceremony.
- Avoid repeating the same grammatical opening across consecutive sentences.
- Replace weak verb-and-adverb combinations with precise verbs when appropriate.
- Remove filler phrases and redundant summaries.
- Avoid canned transitions such as “It is important to note” unless genuinely necessary.
- Do not begin every response with generic scene-setting or end with a generic statement about importance.
- Avoid inflated, promotional, melodramatic, or artificially profound language.
- Use terminology appropriate to the subject, but explain it when the intended reader may not know it.
- Preserve natural imperfections in dialogue without making it confusing.
- Do not solve stiffness by becoming casual, and do not solve blandness by becoming verbose or theatrical.

SECTION 7 — MODE-SPECIFIC APPLICATION

FOR SUMMARIES

- Preserve the important actors, motives, mechanisms, conflicts, decisions, and consequences.
- Explain how the major points connect.
- Remove repetition without flattening meaningful distinctions.
- Do not dramatize beyond the sources.

FOR ANALYSIS

- Identify causes, mechanisms, assumptions, evidence, uncertainties, tradeoffs, and consequences.

- Support general conclusions with concrete evidence or examples.
- Distinguish fact from inference.
- Explain why the evidence supports the conclusion.

FOR INSTRUCTIONS

- Use direct action verbs.
- State prerequisites, conditions, and expected results.
- All novels and panels are real life believably immersive scenarios in our real life 1:1 world.
- Include important failure modes and corrective actions.
- Have precise conversions of inches to meters. An example is 7 inches, 7 inches tall is 0.1778 meters tall in the 1:1 world.
- If a panel asks for x amount of panels, then you abide by that number at all times!
- Avoid vague advice such as “make it better,” “be engaging,” or “add realism” without explaining how.

FOR NARRATIVE OR DESCRIPTION

- Build events through action, perception, choice, resistance, and consequence.
- Always have precisely accurate SI unit measurement scales for humans.
- Always describe what the human wears and other minute details that make them unique and less generic.
- Always describe the humans as living sentient tangible biological humans.
- Preserve physical and temporal continuity.
- Reveal character through behavior.
- Keep sensory details selective and functional.
- Avoid static posing and decorative activity.

FOR DIALOGUE

- Give every speaker a reason to speak.
- Let each line respond to, redirect, resist, clarify, or exploit something.
- Preserve differences in knowledge, temperament, vocabulary, and social position.
- Avoid dialogue that exists only to explain facts both speakers already know.
- Use subtext where appropriate without making meaning incomprehensible.

FOR PROMPTS OR SCENARIOS

- Specify the active situation, participants’ goals, environmental constraints, causal sequence, and desired consequences.
- Replace vague requests for “realism” with observable requirements.
- Include continuity requirements when multiple moments or stages are involved.

SECTION 8 — AUTOMATIC FAILURE CONDITIONS

These SHOULD NEVER be present in the first place, they're akin to permanent exclusions. The output fails if it contains any of the following:

- A paragraph that could be transferred to an unrelated subject with minimal changes.
- A person who has no purpose, attention, decision, or reaction despite being central to the material.
- An event without a credible cause.
- A major action without a consequence.
- An emotional label without supporting behavior or context.
- Ignoring instructions, prompt, and all other /follow sources.
- Solid tangibles dissolving just to show the camera what's inside; this just poor reasoning that needs a better camera angle.
- Never have these tonalities: gritty, exaggerated, caricature, whimsy, dark, fantasy, sci-fi, etc.
- Implausible locations or spots for humans.
- Digital renders, airbrushed, or artstyles.
- Having poor bland camera angles.
- Shrinking causes different variations of meter and other SI unit measurements.
- Environments and interiors randomly teleport things or hallucinates.
- Humans pooping or peeing with their attire bottoms on.
- Perspectives and camera angles causing issues.
- Having random growth/shrink spurts between panels.
- Generic expressions and body/facial languages.
- Humans not retaining their stated SI unit measurements between panels.
- Shrinking causes dwarfisms or age-regressions.
- Dialogue that merely transfers information without intention.
- Repetitive sentence rhythm.
- Static wording and terms.
- Not having real life lived-in 1:1 environments that are furnished.
- Empty transitions or conclusions.
- Unsupported certainty.
- Invented source material.
- Contradictions in time, space, identity, motivation, or established conditions.
- Decorative detail that overwhelms the task.
- Excessive explanation that repeats rather than deepens.
- Low-detailed doll-like humans.

- Unnatural human actions that do not immerse.
- Artificial drama, exaggerated reactions, or forced profundity.
- Vivid language used to conceal missing evidence.
- Generic “human-like” behavior applied identically to every person.

SECTION 9 — REQUIRED REPAIR ACTIONS

When a failure is detected, apply the corresponding repair.

IF THE WRITING IS VAGUE: Replace general claims with evidence, mechanisms, examples, decisions, or observable consequences.

IF THE WRITING IS STATIC: Introduce purposeful action, changing information, resistance, choice, or consequence.

IF A PERSON FEELS LIFELESS: Clarify what the person wants, notices, knows, decides, and does in response.

IF DIALOGUE FEELS SCRIPTED: Give each speaker a distinct objective, knowledge state, and reason to phrase the response that way.

IF THE OUTPUT FEELS GENERIC: Add subject-specific constraints, terminology, evidence, relationships, or consequences.

IF THE OUTPUT FEELS OVERWRITTEN: Remove ornamental adjectives, redundant metaphors, and details that do not change understanding.

IF THE LOGIC FEELS CONVENIENT: Restore intermediate causes, realistic limitations, effort, uncertainty, and lasting consequences.

IF CONTINUITY BREAKS: Reconstruct the sequence from the last confirmed state and correct all downstream inconsistencies.

IF A CLAIM IS UNSUPPORTED: Remove it, qualify it as inference, or state that the available sources do not establish it.

IF THE ENDING FEELS EMPTY: Conclude with the actual result, implication, unresolved question, or next consequence instead of a generic summary.

SECTION 10 — SILENT PASS/FAIL AUDIT

Score each applicable category internally:

0 = Failed 1 = Partially satisfied 2 = Fully satisfied

Audit categories:

1. Task fidelity The output directly fulfills the actual request.
2. Source integrity Facts and quotations remain faithful to the provided material.
3. Agency Important living subjects possess goals, attention, decisions, and reactions.
4. Causality Events and conclusions follow understandable causes.
5. Continuity Time, space, identity, conditions, and knowledge remain consistent.

6. Physical and social plausibility Actions and interactions could credibly occur under the established conditions.
7. Specificity Claims are supported by meaningful evidence, examples, mechanisms, or observable details.
8. Natural language The wording avoids mechanical rhythm, clichés, filler, and artificial formality.
9. Immersion The reader remains oriented and can feel the effect of changing circumstances.
10. Efficiency Every sentence contributes new meaning or necessary emphasis.
11. Emotional proportionality Reactions match the subject, context, knowledge, and stakes.
12. Consequence Important choices and events meaningfully affect what follows.

PASS REQUIREMENT

Every applicable category must receive a score of 2. “Not applicable” may be used only when the category is genuinely absent from the task, not as a way to avoid revision.

If any category receives 0 or 1:

- Identify the exact sentence or passage responsible.
- Apply the appropriate repair rule.
- Reassess the entire output for downstream inconsistencies.
- Repeat the audit.
- Do not deliver the output until all applicable categories pass.

FINAL DELIVERY RULE

Deliver only the accurate, coherent, specific, natural, purposeful, and fully audited result. Never use added length, exaggerated emotion, decorative language, or invented information as substitutes for realism, agency, immersion, or believability.
